Does Distance Still Matter?

Revisiting Collaborative Distributed Software Design

// Studying the design activities of colocated and distributed software designers revealed that despite comprehensive technological improvements, distance still matters. To ensure effective distributed software design, designers must consider extra (nontechnical) details. //

Companies engage in global software engineering (GSE) to reduce development time and costs. Companies also head toward cross-site distribution of their development work to take advantage of proximity to markets and customers.¹ However, working at a distance might compromise the effectiveness of GSE.

There are two important challenges to making GSE successful. Almost two decades ago, Gary Olson and Judith Olson raised these challenges:²

- *technological challenges* raised by the need for efficient, effective remote-collaboration tools and media; and
- *social challenges* raised by differences in local context, culture, language, and trust between collaborators.

They predicted that future technological advances will reduce the effect of the technological challenges. But they also predicted that working at a distance will rarely succeed owing to the inevitable differences raised by the social challenges. However, advances in communication and collaboration technologies raise the question of whether distance still matters.

One of the key activities of software engineering is software design. It comprises discussing requirements, exploring the problem domain, and making design decisions. When globalized, software design could become less effective. Several design activities could be affected, including

- design modeling (representation),
- design reasoning (about problem-domain and solution-domain design aspects), and
- design communication.

Also, lack of awareness (understanding others’ activities) and problems with communication media might threaten the success of distributed software design.

Many researchers have explored the impact of distance on collaborative work. James Herbsleb argued that colocation fosters communication...
because developers are aware of who is around and who is doing what. In contrast, being unable to share resources and see what is happening at the other sites hinders communication across different locations.

Pernille Bjørn and her colleagues investigated whether distance still matters for distributed collaboration. They found that the social challenges form an obstacle to achieving effective work between remote collaborators.

Demetrios Karis and his colleagues performed studies of remote collaboration at Google. They found that the use of video conferencing and video portals contributes to the success of remote collaboration by

- providing presence and status information,
- helping to establish mutual trust and common ground, and
- preventing misunderstandings.

However, when it comes to remote design collaboration, Karis and his colleagues highlighted that developers at Google found collaboration over video conferencing and video portals a pale imitation of face-to-face interaction. Moreover, the developers complained that the video portals at Google lacked a shared drawing tool to facilitate sketching, designing, and brainstorming.

This conforms with what David Budgen stated in his paper “The Cobbler’s Children”: many modeling tools do not serve the purpose of software design and rarely support realistic software design practices. According to Budgen, modeling tools should preserve the flexibility and simplicity of whiteboards and provide proper support for distributed designers at different locations.
COLLABORATIVE DESIGN MULTIPLE-CASE STUDY (Cont.)

Several researchers have proposed next-generation design-support tools that are in line with Budgen's guidelines. One of these tools is OctoUML. OctoUML allows mixed informal modeling (sketching) and formal modeling and supports collaborative distributed software design.

To answer the question posed in our article’s title, a deep investigation of current practices of collaborative software design is required. To do so, we analyzed a collaborative-design multiple-case study based on two exploratory cases. Details regarding that study are in the sidebar.

How Distance Affects Design Decisions

First, let’s look at the type of design decisions that were made and see whether they differed between distributed and colocated design sessions. The graphs in Figure 1 indicate that the colocated designers discussed more design decisions in the problem domain than the distributed designers did. More details on how these design decisions were made are available at http://rodijolak.com/DoesDistanceStillMatter.html.

The decisions in the problem domain consisted mainly of assumptions, as shown in Figure 2. One of the reasons that might have allowed colocated designers to discuss more problem domain design decisions is that they implicitly knew (via facial expressions and body language) whether a specific assumption was mutually understood. In a collaborative process, the conversation can continue only when the collaborators mutually establish what they know. Distance obstructs the process of establishing a mutual understanding of the problem domain between distributed designers. When one designer makes an assumption...
and implicitly perceives that the co-located partner did not understand that assumption, that designer might rephrase the assumption or build more knowledge around it.

In contrast, distributed designers usually do not see each other when discussing assumptions. Hence, the perception of having a mutual understanding (via body language) was rarely possible. Indeed, the distributed designer making an assumption often implicitly considered that the remote partner understood it, thus producing fewer problem domain design decisions.

Technical issues also affected the distributed design discussions—e.g., through blurriness of the voice and instability of the communication medium. Lack of awareness could have also led to fewer problem domain design decisions in the distributed setting. This is because not perceiving another person’s actions makes it difficult to initiate contact and often leads to misunderstanding of communication content and motivation.³

How Distance Affects Collaborative Communication

The graphs in Figure 3 show how distance could affect communication in distributed design. We see that distributed teams had fewer creative-conflict discussions but more conversation. Creative-conflict discussions can promote software design reasoning and enhance the effectiveness of group tasks.⁹

The creative-conflict problem-solving discussion skill comprises
two major subskills: Mediate and Argue (see Figure 4). Argue comprises different actions (agree, disagree, offer an alternative, propose an exception, etc.). Distributed designers argued less, as shown in Figure 5. One of the reasons for fewer arguments—and hence fewer creative-conflict discussions—might have been lack of trust. Collocated designers share experiences and context, which helps them to develop trust. Trust is needed for collaborators to be able to challenge each other without frustrating collaboration. Distributed settings can complicate establishing trust and might compromise reliability between the remote collaborators.12

Another reason could have been lack of common ground—i.e., the knowledge that the designers are aware of and have in common—in distributed design sessions. When common ground is missing, it might affect distributed collaborators’ activities and context, which helps them to develop trust. Trust is needed for collaborators to be able to challenge each other without frustrating collaboration. Distributed settings can complicate establishing trust and might compromise reliability between the remote collaborators.12

As we mentioned before, more conversation happened between the distributed designers than between the colocated designers. To explain this, we recall that conversation comprises three major subskills: Maintenance, Task, and Acknowledge (see Figure 4). Distant collaboration requires more management overhead and discussion about work coordination. Lack of awareness among distributed collaborators also raises more task discussions and maintenance discussions. For example, the distributed designers summarized design decisions to confirm knowledge of what they had done so far. Summarizing also helped them understand the intention of their partners.

In addition, distributed designers had fewer Inform (see Figure 4) discussions than the colocated designers. This indicates that distributed designers tend to give less information about their decisions, which leads to less active discussion of the essence of and rationale for those decisions.

The Challenges of Distributed Design

The distributed designers reported the following challenges.

Technological Challenges

The designers considered connection instability as a challenge. Network problems and high CPU use in the client machines interrupted several design sessions. These devices were simultaneously running OctoUML, screen- and voice-recording software, and telecommunication software, which overloaded them. Consequently, the designers had to wait until communication was reestablished. This situation can be prevented by avoiding such overloads.

Moreover, the distributed designers complained about the quality of voice communication. This depends on different factors: the quality of the Internet connection, the distance from the microphone, and the volume of the speakers. This problem can be alleviated by adopting advanced communication infrastructures, a high-speed Internet connection, and advanced voice management tools.

Nonetheless, many organizations fail to keep pace with technological advances and therefore fail to manage the aforementioned challenges.

Social Challenges

First, the designers perceived the lack of awareness as a challenge. In particular, they felt that the inability to interpret eye contact, body language, and facial expressions affected their decisions and activities. For instance, one designer said that because he could not see how
his partner reacted to his proposals, he was unable to decide how to act appropriately. Each designer was unaware of what the collaborating designer was doing and which part of the system that designer was talking about or pointing to.

Second, the designers also perceived the lack of trust as a challenge. In particular, the designers felt that not knowing their collaborator beforehand could have affected their discussions and work.

Other Challenges
The design assignment per se was perceived as a challenge. We believe this confirms our process of thoughtfully planning the assignment to simulate real-world software design situations. This planning took into account ideation, problem domain exploration, and design solution decisions.

The geographical distribution of collaborating partners in practice still raises social and technological challenges. Thus, practitioners should carefully consider whether the distribution is applicable and weigh the benefits of
technology deliberately. To support distributed designing, for instance, modern collaborative-design environments focus on the consistent, real-time sharing of diagrams. However, social awareness, such as the ability of designers to relate to each other through pointing, gaze, and gestures, remains missing.

The designers in our study indicated challenges in distributed collaborations that are beyond the scope of tooling. In particular, in contrast with locally collaborating teams, distributed designers did not know their collaborators beforehand. Hence, they had to build professional and personal trust during the experiment.

On the basis of our results, we encourage software design practitioners aiming to collaborate remotely to consider the following:

- Establish trust via arranging personal or virtual meetings or social events before the remote design sessions.\(^5\)
- Establish common ground via exchanging interests, experiences, expertise, and beliefs between distributed designers.
- Introduce explicit triggers for creative-conflict discussions into the collaboration process.

Furthermore, we recommend that the developers of computer-supported cooperative work (CSCW) tools for software design should support awareness by adapting technology to provide immersive telepresence experiences.

Software design requires extensive exploration of the problem domain and context, and leads up to making critical design decisions about software systems. Moreover, collaborative software design is tightly coupled work that requires either more frequent or more complex interactions.\(^2\) Because of these aspects of software design and because the current technology is still incapable of fully mitigating the social challenges of remote collaboration, we suggest that distance still matters.\(^6\)
